Summary. Functional food components are usually related with disease prevention. Cynarin is one of the biologically active functional food components which is the major dicafeoylquinic acid derivative found in artichoke. Although artichoke contains very low amount of cynarin, it still duplicates the effects of artichoke. Cynarin is one of the biologically active functional food components that have potential effects on choleretic and cholesterol lowering, hepatoprotective, anti-atherosclerotic, anti-HIV, antioxidative, anti-diabetic, anti-carcinogenic and immune modulator activity. To sum up, more molecular, clinical and epidemiological studies on cynarin is necessary to be able to use it as a disease preventive agent.

Key words: cynarin, artichoke, functional food, caffeoylquinic acid

Introduction

Discovering biologically active functional food components and their effects are important for chronic diseases prevention. Most studies on artichoke extracts and health effects are related with antioxidant potential of phenolic continents such as chlorogenic acid, caffeic acid, cynarin (CYN) and flavonoids (1-3). Mono- and di-cafeoylquinic acid derivatives are major polyphenols of artichoke. CYN is the major dicafeoylquinic acid derivative of artichoke and it duplicates many effects of artichoke despite the very low amount of CYN content. In mid-century, CYN has been isolated from artichoke leaf by Italian scientists (4). Firstly, it was isolated as active principle of artichoke and called as 3,5 dimetoxy 1,4 dihydroxycyclohexane carboxylic acid (5). Afterwards, caffeoylquinic acids were classified in 1973 and the nomenclature have been changed in 1976 by IUPAC (International Union of Pure and Applied Chemistry). According to this new recommendation, when CYN was called as 1,5-O-dicafeoylquinic acid, it had been changed as 1,3-O-dicafeoylquinic acid (6). CYN is the main derivative of caffeoylquinic acids which is find in both leaves and heads of artichoke (7). Methanolic extracts of artichoke contains about 1.5% CYN (3, 8). In addition, it is a key constituent of the aqueous dry extracts used in many artichoke preparations since it resists against trypptic digestion, boiling, acidification (9). Moreover, it is present only in traces in fresh or carefully dried leaf and it is formed by transesterification from 1,5-O-dicafeoylquinic acid in hot water during the extraction process (10). Furthermore, CYN content is duplicated in cooked baby artichokes and this may be attributed to isomerization of dicafeoylquinic acid with the heat and the esterification of caffeic acid, increasing the CYN content (11). Researches about potential health effects of CYN can be summarized as choleretic and cholesterol lowering, hepatoprotective, anti-atherosclerotic, anti-HIV, antioxidative, anti-diabetic, anti-carcinogenic and immune modulator activity (12-14) (Table 1).

**Potential health effects of CYN**

**Choleretic and cholesterol lowering effects**

The study with rats demonstrated that CYN shown a significant reduction in serum cholesterol concentrations (15). The study conducted with patients with resistant primary hypertriglyceridemia shown that 750 mg and 1500 mg CYN reduced the total serum lipids, triglycerides and phospholipids concentrations (10). In contrast another study shown that the treatment with 250 mg or 750 mg CYN for three months of have no effect on serum cholesterol and tri-
glyceride concentrations of familial type IIa or type IIb hyperlipoproteinaemia patients (16). Otherwise, clinical studies showed that 60 mg - 1500 mg daily doses of CYN is effective in lowering serum cholesterol and triglyceride concentrations (14).

**Hepatoprotective effects**

Azdet et al (17), reported that CYN shows hepatoprotective activity against CCl4 toxicity in rat hepatocytes. Another study with rat hepatocytes indicated that 3 µM CYN reduced t-BPH induced MDA production and EC50 value of CYN was 15.2 µg/ml (9, 18).

**Anti-atherosclerotic effects**

Endothelial nitric oxide synthase (eNOS) is responsible for nitric oxide (NO) synthesis and it is established that CYN have not any effects on increasing eNOS promoter activity until 100 µM (19). While eNOS has vascular protective effects induced nitric oxide synthase (iNOS) has proinflammatory effect. The study with artichoke leaf extract indicated that CYN, cyanadin, cynaroside and luteolin reduced iNOS activity and CYN was the most effective with 3 µM (20).

**Anti-HIV effects**

The research results that CYN inhibits HIV-1 replication in human T-cell leukemia (MT-2) cells with 25 µM (half maximal effective concentration-EC50) and inhibits growth of the MT-2 cells with 250 µM (median lethal dose-LD50) (21).

**Antioxidative effects**

It is reported that hydroxyl groups on the aromatic ring are responsible for the antioxidant activities of phenolic compounds, the higher number of hydroxyl groups means that higher antioxidant activity. In addition, the ortho or para position of the second hydroxyl group is increased the antioxidant activity. CYN has both of this properties and it has highest antioxidant activity compare to other compounds such as chlorogenic acid, 1-caffeoylquinic acid, cynaroside, luteolin rutinoside, apigenin rutinoside, mostly found in artichoke (22). Jun et al (23), have been shown that CYN has strong antioxidant activities against DPPH (1,1-diphenyl-2-picrylhydrazyl) and ABTS (2,2’-azi-no-bis(3-ethylbenzothiazoline-6-sulfonic acid)) radicals. Furthermore, it is demonstrated that antioxidant activity of CYN is stronger than trolox standard (half maximal inhibitory concentration-ICso: 12 µM, 25 µM respectively) by scavenging ABTS radicals and stronger than both trolox standard and caffeic acid (ICso: 40 µM, 50 µM, 70 µM respectively) by inhibiting DPPH radicals. CYN also inhibited linoleic acid oxidation, scavenged the hydroxyl radicals and superoxide anions. It is also reported that on 3T3 cells, 51 µM CYN inhibited oxidative stress (75%) by iron (Fe2+) and 45 µM CYN inhibited oxidative stress (72%) induced by AAPH (2,20-azobis(2-amidinopropane)dehydrochloride) (24). Overall, the antioxidant activity of CYN depends on its’ ability to scavenge ROS.

**Anti-diabetic effects**

Potential antiglycative effects of CYN has been shown in the bovine serum albumin-glycose system and it exhibited significant advanced glycation end products (AGE) inhibitory ability in a dose dependent manner (3 µM - 40 µM) (25).

**Anti-carcinogenic effects**

It is indicated that CYN does not have significant difference on the HeLa cells until 400 µM (21). On the other hand, CYN has a cytotoxic effects at the rate of about 20% on leukemic cells (26). Another study showed that CYN affects normal fibroblast skin cells (FSF-1), telomerase-immortalize mesenchymal stem cells (hTERT-MSC) and cervical cancer cells (HeLa) on cell proliferation in a dose dependent manner and 500 µM determined as cytotoxic concentration (27).

**Immune modulator effects**

In response to certain external stimulation T-cells initiate immune activity. Both “positive” and “negative” immune responses are important for maintaining T-cells in a healthy condition. Thus, both “over-active” and “under- active” immune responses are pathological and there are many autoimmune disease examples of “over-active” immune responses. Another research about this issue shows that CYN is a potential immune modulator agent due to blocking effects on CD28 which is T-cell receptor immune cells (28).
Conclusion

Functional food components are usually related with disease prevention. So, the importance of functional food components and their potential health effects are increases day by day. Healthy nutrition is related with reduced disease risk and increased life quality. So, it’s aimed to use the potential beneficial health effects of some most consumed foods for prevention from chronic diseases. Thus, knowing the effects of biologically active food components and their mechanisms is important to develop safety consumption suggestions and to improve personalized recommendations. CYN is one of the biologically active functional food components that have potential effects on choleretic and cholesterol lowering, hepatoprotective, anti-atherosclerotic, anti-HIV, antioxidative, anti-diabetic, anti-carcinogenic and immune modulator activity. To sum up, more molecular, clinical and epidemiological studies on CYN is necessary to be able to use it as a disease preventive agent.
